

Business, Economics, and Scaling

Monetization Model

NeuroTriage AI is designed as an enterprise software solution that integrates seamlessly into the hospital's existing PACS workflow. The product is licensed to hospitals as an optional AI-enabled stroke triage module, allowing healthcare providers to enhance their existing imaging infrastructure without replacing their current systems.

Hospitals choosing to enable this capability pay an annual enterprise license fee, which includes software updates, model improvements, technical support, and performance monitoring. This licensing approach provides a predictable revenue stream for the product provider while allowing hospitals to adopt AI capabilities with minimal disruption to their existing workflow.

Value Logic

NeuroTriage AI creates value by improving emergency workflow efficiency rather than replacing radiologists.

Stakeholder	Value Created
Patients	Earlier identification of suspected intracranial hemorrhage, enabling faster diagnosis and treatment.
Radiologists	Intelligent worklist prioritization, allowing critical studies to be reviewed earlier while reducing manual effort.
Hospitals	Improved emergency response, better utilization of radiology resources, and enhanced quality of patient care without disrupting existing workflows.
Product Provider	Long-term customer relationships with continuous product enhancement through clinician feedback and software updates.

The product delivers value by enabling faster clinical decision-making while preserving clinician oversight and patient safety.

Cost Drivers

Cost Driver	Examples
Model Development & Integration	AI model development, inference infrastructure, PACS integration, API maintenance, and model updates
Customer Support	Hospital onboarding, user training, technical support, and software maintenance
Data & Operations	Data anonymization, quality validation, performance monitoring, and model retraining
Clinical & Regulatory	Expert validation, pilot evaluations, Human-in-the-Loop review, and regulatory documentation

Effective management of these costs ensures that the value delivered to hospitals continues to exceed the cost of developing, operating, and maintaining the product.

Unit Economics View

NeuroTriage AI requires significant upfront investment in AI development, clinical validation, PACS integration, and regulatory readiness. However, once deployed, the same AI platform can be licensed across multiple hospitals with relatively low incremental deployment cost.

The business model becomes sustainable when the product consistently delivers measurable clinical and operational value while maintaining efficient operational costs. This depends on:

- High clinician adoption.
- Measurable improvements in emergency workflow efficiency.
- Continuous product improvement through real-world clinical feedback.
- Efficient customer support across multiple deployments.

As adoption increases, software enhancements benefit all licensed customers, enabling the product to scale efficiently while improving long-term business value.

Scaling Risks

Risk	Potential Impact	Mitigation Strategy
Latency	Delayed worklist prioritization reduces clinician trust.	Optimize inference performance and deployment infrastructure.
Cost Growth	Increasing infrastructure, support, and maintenance costs as deployments expand.	Efficient resource utilization, scalable deployment architecture, and centralized monitoring.
Workflow Complexity	Different hospitals use different PACS systems and clinical workflows.	Standardized integration APIs and configurable workflow integration.
Governance Burden	Increased monitoring, compliance, and model oversight requirements.	Continuous performance monitoring, periodic clinical validation, and governance reviews.

A phased deployment strategy is recommended, beginning with pilot implementation at a single hospital, followed by expansion to multiple hospitals before extending the platform to support additional neurological conditions and enterprise-wide deployments.
